

HEADLINE: sniff-alignment strength (mean theta coherence) as a function of depth (exploratory; no significant depth effect detected)

HEADLINE: sniff-alignment strength (mean theta coherence) as a function of depth. Per-animal points (gray, n=5 animals after >=30-window exclusion) plus grand mean +/- SEM; overall best-aligned depth (descriptive observation, not a definitive claim) = D5, per-ordinal consistency count 1/5 animals. Companion panel: significant-theta fraction by depth (same convention). Omnibus test for depth-dependence: mixed-effects LRT chi-square=1.822, df=4, p=0.768; Friedman chi-square=1.760, df=4, p=0.780, Kendall's W=0.088 -- BOTH NON-SIGNIFICANT (alpha=0.05; omnibus_significant=False); no Holm-corrected post-hoc comparisons were run (PROH-006/OUT-016). This is an exploratory, non-causal characterization: no significant depth effect was detected in this dataset (absence of evidence is not evidence of absence); depth does not 'cause', 'determine', or 'control' alignment strength here.
